TITLE: Comparing the resistance to wear of various tool materials in broaching of cast-iron parts

PERIODICAL: Referativnyy zhurnal, Mashinostroyeniye, no. 23, 1962, 86, abstract 23B499 ("Avtomob. prom-st'", 1962, no. 6, 40)

TEXT: Tests were carried out with the following six sintered carbide grades on specimens of grade C 421-40 (S421-40) cast iron of HB 210 - 217 hardness: BK4 (VK4), BK 6 M (VK6M), BK 8 (VK8), TT 7 K12 (TT7K12), T5K10 (T5K10) and T 15 K6 (T15K6), and also with P 18 (R18) high-speed steel. The tests were conducted at γ - 1.3, 5, 6, 8, 10, 15, 20 and 30 m/min; S = 0.2 m; B = 4.5 mm. Of all these tool materials, VK6M showed the maximum service life at all cutting speeds and is recommended to be used for the broaching of cast-iron parts. There are 2 figures and 1 table. ✓

AUTHOR: Zitnansky, Bohumil (Zhitnyanski, B.)

TITLE: A study of the transition of chromium and sulfur into welding filler metal

SOURCE: Jaderna energie, no. 3, 1964, 85

TOPIC TAGS: isotope exchange, welding rod, welding electrode, welding metal filler, chromium, sulfur, welding, filler metal, Cr⁵¹, S³⁵

ABSTRACT: The transition of chromium and sulfur into welding filler metal was studied with the help of Cr⁵¹ and S³⁵. Activated chromium and sulfur were in the electrode coating. Activation was effected by a simultaneous immersion of the electrodes in a solution of Cr⁵¹ and S³⁵ with isotope exchange. Radiometric evaluation was done by a double measurement. The activity of chromium was established by a gamma scintillation counter, while the S³⁵ radiation was measured with a beta scintillation counter without window. Certain relations were established for the welding electrode. A large amount of chromium evaporates out of the electric arc under given welding conditions, whereupon the relatively

Card 1/2

ACCESSION NR: AP4019093

marked transition of chromium for the given chromium-nickel electrode takes place in that case when the chromium is found in the electrode coating. In a contrary case, the chromium losses are more substantial. Sulfur transforms from coating into metal almost completely. TEXT: The tests were carried out in the FA-61-a (GL-61-a) high-frequency melting-tempering apparatus of the Institut stali (Steel Institute). The heating element was a graphite crucible 180 mm high, with 100 mm internal diameter, and 15 mm wall thickness. Several operation conditions were tried: different amperage of the anodic current, different forms of holding with a definite amperage of the anodic current. The operation was controlled by the holding under cover after the current had been switched off, and also the production compositions of the mixture. The preliminary investigation into the production of foam glass in graphite molds with a high-frequency current yielded results showing that uniform foaming is inhibited by a

TITLE: A method of calculating the temperature field and the crystallization front in the zone of secondary cooling in square section ingots during continuous teeming of steel.

PERIODICAL: Referativnyy zhurnal. Metallurgiya, no. 12, 1961, 60, abstract 12V367 ("Sb. nauchn. tr. Gos. n.-i. i proyektn. in-t metallurg. prom-sti "Giprostal", 1960, no. 2; 145 - 151)

TEXT: A method is described to calculate the temperature fields and crystallization front in secondary cooling zones of square-section ingots during continuous teeming of steel. It is noted that the accuracy of calculation by this method is sufficient for practical purposes and that results of calculating the temperature field can be applied to investigate the effect of cooling conditions on mechanical stresses in the crust and on the quality of the ingot. By varying the values of dimensionless criteria of similarity, a sufficiently complete table of data can be obtained for the depth of the liquid phase for parameters of different values, and corresponding recommendations can be given as to the height of

"Combined Therapy of Extensive Burns by the Application of
Fibrin Films," by R. I. Zhitnyuk, "N" Hospital (chief, M. A.
Nesterov), *Vestnik Khirurgii imeni I. I. Grekov*, Vol 78, No 4,
Apr 57, pp 94-95

The author gives the medical history of one patient suffering from
burns on 72% of his body surface as a result of a compressed gas explosion
in a closed space.

On arrival at the surgical department, the patient's condition was
serious: blood pressure 85/44 mm Hg, heart beat weak, etc. The condition
of the patient was immediately improved by morphine administration, blood
transfusion, etc.

After getting the patient out of shock, the burnt surface of the patient's body was treated under ether anesthesia by gauze tampons moistened with furacilin (5-nitro-2-furfurylidine-semicarbazone). On the burnt surface perforated fibrin films were laid and these were later covered by gauze also moistened with furacilin. Every 2 days these gauze coverings were moistened with furacilin solution without removing them from the burnt surface. Infusion of 5% glucose in physiological solution, penicillin (30 million units), streptomycin (15 g) and food rich in proteins and vitamins was prescribed.

After 15 days the fibrin films were removed, and portions of dry skin with good epithelialization were seen. Necrotic tissue sloughed off in 32 days, and the patient was discharged after 2 1/2 months.

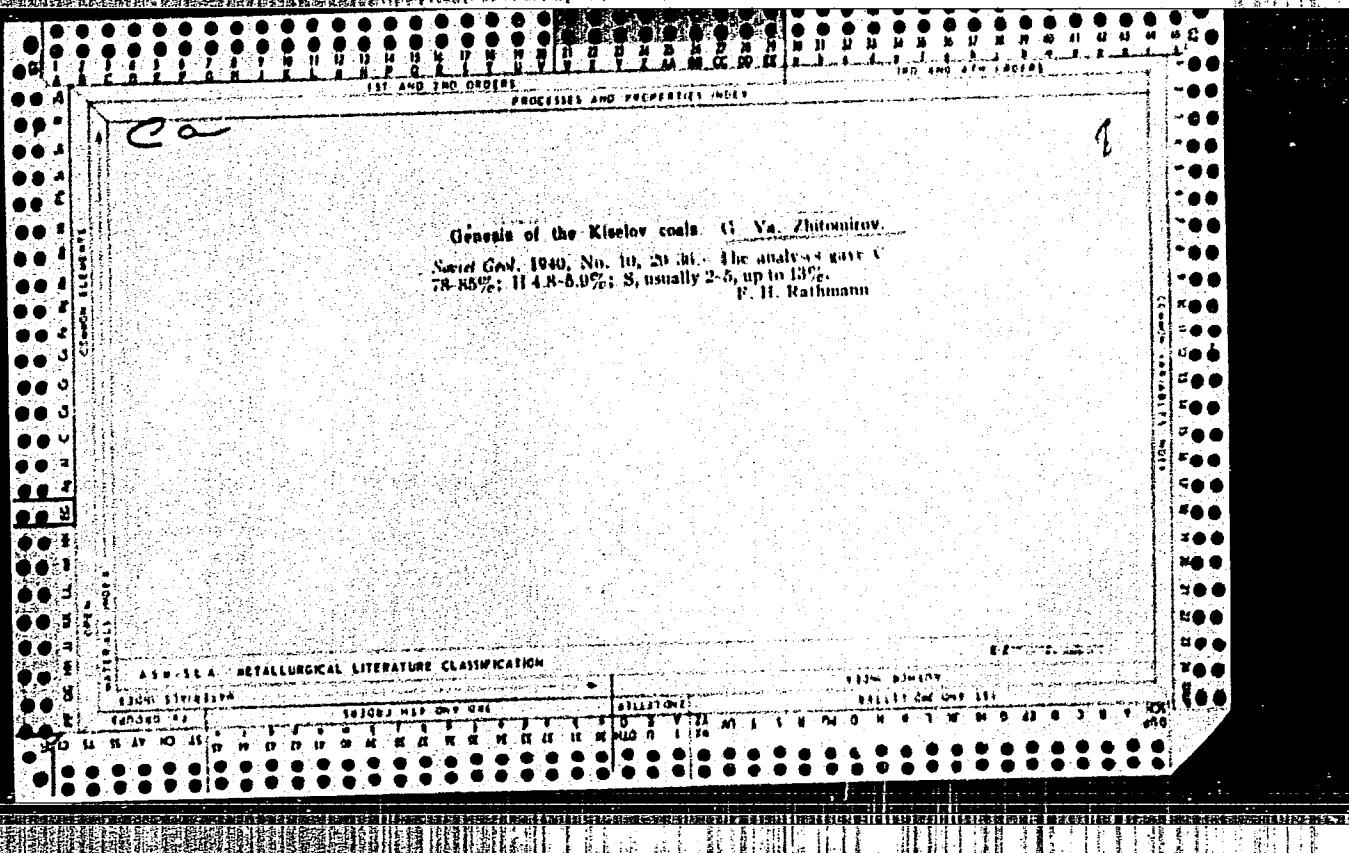

The author concludes that this case history demonstrates that a timely application of combined therapy using large quantities of antibiotics, blood transfusion, and fibrin films brings about a significant decrease in the possibility of a fatal outcome in cases of extensive burns. (U)

TITLE: Radiation stability of foamed glass

SOURCE: Steklo i keramika, no. 5, 1963, 16-17

TOPIC TAGS: foamed glass, composition, service temperature, mechanical strength, radiation stability, radiation, foaming agent

ABSTRACT: The radiation resistance of two types of foamed glass has been studied. The first type was prepared from 90 to 95% alkali window glass (71.5% SiO₂, 1 to 1.5% Al₂O₃, 7.5 to 8% CaO, 3 to 3.5% MgO, 15% Na₂O) and 10 to 5% Al₂O₃, TiO₂, or ZrO₂, with the addition of 0.5 to 1% SiC or carbon black, or 4% MnO as foaming agents. The second type was prepared from 70 to 80% nonalkali barium glass (60.5% SiO₂, 14.6% Al₂O₃, 16.2% CaO, 8.7% BaO, + 2% Fe) and 30 to 20% Cr₂O₃ or ZrO₂, with the addition of 0.5 to 1% SiC or carbon black. The approximate service temperature of the glasses is 600 to 800°C; the highest compressive strength, 51.7 to 74.4 kg/cm², is exhibited by specimens produced with use of SiC. The glasses were irradiated with thermal neutrons for 84 hrs (total flux about 10¹⁸ neutron·cm⁻²)

Card 1/2

19

L 10522-63

ACCESSION NR: AP3000392

and subjected to compression tests. The tests showed that the mechanical strength of the specimens remained almost unchanged. It was concluded that foamed glasses from alkali window glass and TiO_2 or ZrO_2 and from nonalkali barium glass with Cr_2O_3 or ZrO_2 are resistant to radiation and can be used as heat-resistant thermal insulation in equipment exposed to gamma-neutron radiation.

SOV/1653

COVERAGE: This monograph gives a detailed description of climatic characteristics of the Golodnaya Steppe as related to the physicogeographical conditions. With the aid of numerous charts and figures it describes the general conditions, wind regime, dust storms, radiation, cloud conditions, air and soil temperatures, air moisture and drought conditions. An attempt to regionalize the area on the basis of climatological features is also made. There are three Soviet references.

TABLE OF CONTENTS:

Introduction	3
Some Characteristics of Climate Formation	5
Wind Regime	7
Local Winds	20
Number of Dust Storm Days	24
Radiation Regime and Cloudiness	32

Binding properties of crystal hydrates of the sulfate type

ZHURAVLBY AND V. I. SHITOMINSKAYA. APPLIED
(U.S.S.R.), 23 (2) 113-17 (1960). — The work was done

Ibid., 23 [3] 113-17 (1950).—The work was limited to $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$. Differential thermal analysis indicates insignificant endothermal effects at 92°, 128°, and 200°C. and more distinct effects at 104° and 342°. A fine-ground sample was stirred, carefully heated to 104°, and held there for 30 min.; after this, grinding and dehydration of the sample were repeated. The addition of water to a partially dehydrated sample caused setting to start in 3 min. and end in 8 min. Test shapes (55% normal consistency) stored in the open showed tensile strengths of 16.5, 17.7, and 28.7 kg./cm.² after 1, 3, and 7 days, respectively; compressive strengths were 240.0, 240.0, 240.0, and 410.0 kg./cm.² after 1, 3, 7, and 28 days, respectively. The specimens had dense structure and high hardness; their coloration was grayish. After open storage for 1 year, hardness, strength, and color were retained. *Ibid.*, 23 [3] 230-32 (1950).—The investigation was limited to $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$. Endothermic effects recorded at 77°, 104°, and 315°C correspond to the separation of water; those at 741° and 865°, to the dissociation of ZnSO_4 . Crystalline hydrate was heated to 104°, held there for 30 min., then ground fine, again heated to 104°, and held for 18 min. The powder was mixed with 55% water; setting started in 4 min. and was com-

plete in 7 min. Tensile (and compressive) strengths, after open storage for 1, 3, and 7 days, were 3.6 (325.0), 14.0 (622.5), and 11.7 (210.5) kg./cm.², respectively. The structure was dense and the color was grayish green; crystals of considerable size were noted by the unaided eye. Debyograms of the specimen of maximum strength indicate that it consists of uniform crystal hydrate and, on the basis of literature data, that it contains $ZnSO_4 \cdot 7H_2O$ and not $ZnSO_4 \cdot H_2O$. Debyograms of the two-week-old specimen, which had crumbled into powder, indicate the presence of a large amount of $ZnSO_4 \cdot H_2O$ and the absence of $ZnSO_4 \cdot 7H_2O$. Under a microscope, the three-day-old specimen showed good crystallization with $n_D = 1.498$ and $n_D = 1.489$; restriction of the three-week-old specimen could not be determined because of very fine crystallization. During a partial dehydration of $ZnSO_4 \cdot 7H_2O$ the crystalline lattice undergoes such a change that the $ZnSO_4 \cdot 7H_2O$, which is formed during subsequent hydration, is unstable and loses water readily. This loss of water changes the size of the crystals and lowers their adherence with the result that the strength is reduced and the specimen crumbles.

Blending properties of crystal hydrates of the sulfate type
V. F. Khuraviev and V. I. Zhilinskikh (Leningrad Inst.
Technol., Leningrad), *J. Applied Chem. U.S.S.R.* 23,
116-19(1950)(Engl. translation); *Zhur. Prilim. Khim.* 23,
113-17. --The dehydration of $MgSO_4$ was studied with
thermal analysis by use of the Kurnakov pyrometer; dis-
cerned, begins above 600° . Blending tests on powder, partially
dehydrated $MgSO_4$, show it commences to set in 3 min. and
setting is complete in 6 min. After storage in air for one
year, samples retained hardness, strength, and color. Industrial
utilization of $MgSO_4$ as blending material is recom-
mended. M E McMahon

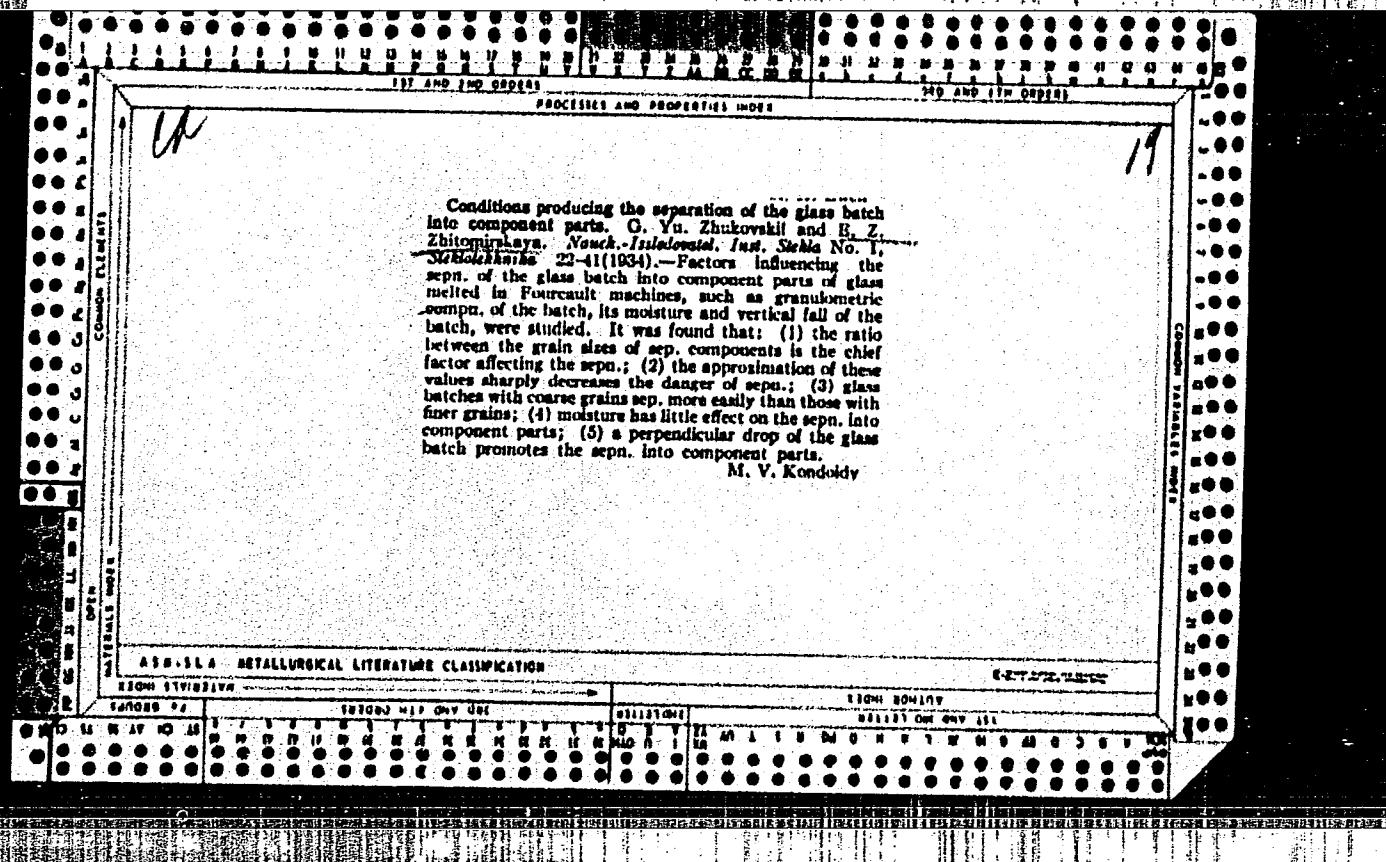

Binding properties of crystal hydrates of the sulfate type.
V. P. Zhuravlev and V. L. Zhigunskaya. *J. Applied
Chem. U.S.S.R.*, 23, 237-30 (1950) (English translation);
Zhur. Priklad Khim., 23, 230-2 (1950); cf. *C.A.*, 43, 3141c.
When $ZnSO_4$ powder is mixed with H_2O , setting is very
rapid and hardening very intense; max. strength is found
after three days; in the air white spots appear, and gradu-
ally merge, and the strength of the samples drops to zero.
X-ray analysis shows that the decrease in strength of hard-
ened samples is due to the spontaneous elimination of H_2O
from the crystal hydrate. Partially dehydrated $ZnSO_4$ has
marked binding properties and an extremely high mechan-
ical strength (during the initial period of hardening).

Binding properties of crystallized hydrates of the sulphate type. V. N. Zhuravlev and V. I. Shchegolev. Usp. Khim., U.S.S.R., 1961, No. 112-117.—Endothermic effects during the heating of $MgSO_4 \cdot 7H_2O$ were observed at 92°, 120°, 164°, 200°, and 343°, and it may be assumed that at 343° the last mol. of water is given up by $MgSO_4$. Partly-dehydrated $MgSO_4 \cdot 7H_2O$ binds very quickly. Cubes (3×3×3 cm.) made from paste show after 1, 3, 7, and 28 days the tensile strengths 2164, 177, 287, and compressive strengths 240, 240, 240, and 410 kg. per sq. cm. High strength, hardness, quick binding, and colour of products suggest that dehydrated $MgSO_4 \cdot 7H_2O$ may be applied for industrial use. J. R. J. ZAAA.

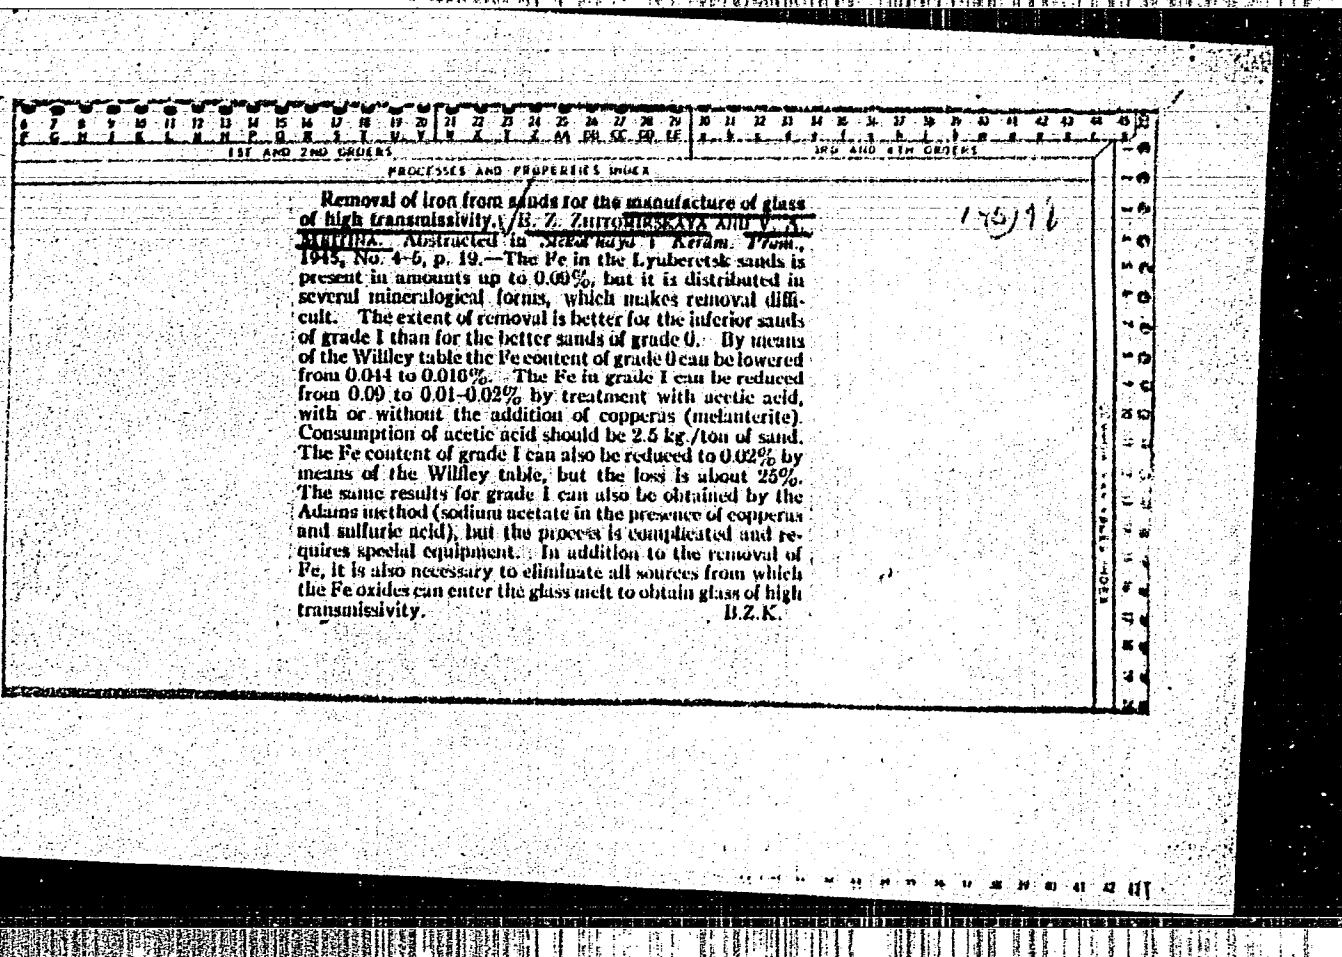

Removal of iron from sands for the manufacture of glass of high transmissivity. B. G. ZHURMINSKAYA AND V. A. MALTSEVA. Abstracted in *Scherzinger's Keram. Prom.*, 1942, No. 4-5, p. 16.—The Fe in the Lyuberts'k sand is present in amounts up to 0.002%, but it is distributed in several mineralogical forms, which makes removal difficult. The extent of removal is better for the inferior sands of grade I than for the better sands of grade 0. By means of the Willey table the Fe content of grade 0 can be lowered from 0.044 to 0.016%. The Fe in grade I can be reduced from 0.039 to 0.01-0.02% by treatment with acetic acid, with or without the addition of copperas (metanterite). Consumption of acetic acid should be 2.8 kg./ton of sand. The Fe content of grade I can also be reduced to 0.02% by means of the Willey table, but the loss is about 25%. The same results for grade I can also be obtained by the Adams method (sodium acetate in the presence of copperas and sulfuric acid), but the process is complicated and requires special equipment. In addition to the removal of Fe, it is also necessary to eliminate all sources from which the Fe oxides can enter the glass melt to obtain glass of high transmissivity. B.Z.K.

Importance of granulometric composition of the reducing agent in glassmelting with sodium sulfate. P. N. ZHURAVLEV. Sverdlovsk. I. Keram. Prom., 1948, No. 1-2, pp. 11-13. The effect of the granulometric composition of anthracite in the reduction of sodium sulfate during glassmelting was investigated with a charge calculated to give a glass containing SiO_2 72, Al_2O_3 2, CaO 8, MgO 2, and Na_2O 16%. Melting was conducted at 1350° for only 3 hr. to use the extent of incomplete melting as an indicator of the effect of grain size of coal on the reduction of sulfate. The melting pots had capacities of 100 and 500 gm. of glass melt. The coal was of three classifications: (a) up to 0.2 mm., (b) up to 0.5 mm., and (c) 1.5 to 2 mm. The quantity of coal (85% carbon) was expressed as R , which is C/SO_3 in the batch (in %). The quality of the melt was better for classification a coal. As the quantity of classification c coal is increased, there is a sharp changeover in quality; thus, when R is 14%, the glass is not yet completely free of bubbles, but when R is 10%, there is already discoloration. B.Z.K.

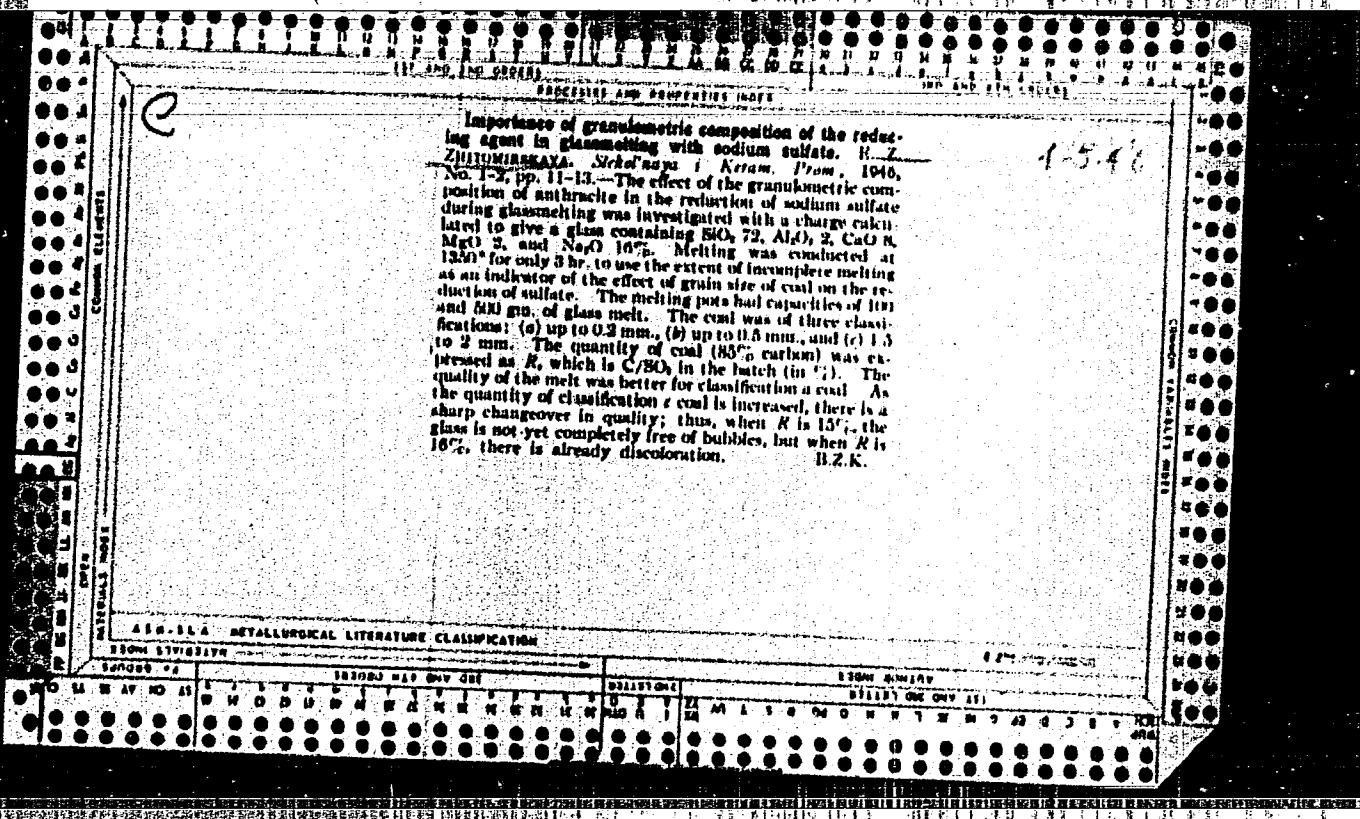

CA

Significance of the particle size of the reducing agent in glass melting with a sulfate batch. Jr. Z. Zhitomirskaya, Sib. nauch. i Tekhn. Press, 1964, No. 1/2, 11-13. — Anhydrite in sizes of 1.0-2.0, not over 0.8, and not over 0.2 mm. was used in glass batches. Generally, deficiency of reducing agent causes glass gall and excess causes discoloration. Coarse reducing agent is more reactive, and smaller quantities of it will cause discoloration. Also the transition from quantities causing glass gall to quantities causing discoloration is more rapid with a coarse than with a fine-grain reducing agent. M. Hoch

C' 16/8
Importance of granulometric composition of the reducing agent in glassmelting with sodium sulfate. R. J. Gurovskaya. Sov. Krem. i Keram. Prom., 1946, No. 1-2, pp. 11-13.—The effect of the granulometric composition of anthracite in the reduction of sodium sulfate during glassmelting was investigated with a charge calculated to give a glass containing SiO_2 72, Al_2O_3 2, CaO 8, MgO 2, and Na_2O 16%. Melting was conducted at 1350° for only 8 hr. to use the extent of incomplete melting as an indicator of the effect of grain size of coal on the reduction of sulfate. The melting pots had capacities of 100 and 500 gm. of glass melt. The coal was of three classifications: (a) up to 0.2 mm., (b) up to 0.5 mm., and (c) 1.5 to 2 mm. The quantity of coal (85% carbon) was expressed as R , which is C/SO_3 in the batch (in %). The quality of the melt was better for classification c coal. As the quantity of classification c coal is increased, there is a sharp changeover in quality; thus, when R is 10%, the glass is not yet completely free of bubbles, but when R is 10% there is already discolouration. BENEFICIATION OF SANDS FROM THE VELIKODVOR DEPOSITS.

E. Z. Zhitomirskaya and E. N. Stepanova. Abstracted in
Stekol'naya i Keram. Prom., 1947, No. 7, pp. 17-18. --
The quartz glass sands of the Velikodvor deposits analyze over
98 SiO₂, about 0.10 TiO₂, up to 0.80 Al₂O₃, and up to 0.28%
Fe₂O₃. Average grain size is 0.25 to 0.3 mm. The most
effective method of treatment is by means of a Wifley table;
this will remove 35 to 45% of the iron oxides (in one case,
the removal was as high as 70%). The remaining content of
iron oxides is 0.05 to 0.12%. The tailings are considerable
but, after the dust has been removed, they can serve in the
production of dark glass. The middlings were not treated
further. Sands which are adulterated with iron in the form
of limonite films on the grains must be treated by washing
with friction in order to remove the iron. This method is
equal to that involving the use of oxalic acid. .B.Z.K.

ZHITOMIRSKAYA, YE. Z.

Dressing of glass sands. E. Z. ZHITOMIRSKAYA
Slekol'naya i Keram. Prom., 1947, No. 5, pp. 1-3, 17.
Pending on the nature of the iron adulteration, glass sands
are classified into types in which the iron compounds are
present (1) in the form of heavy minerals having a specific
gravity greater than 3 (magnetite, hematite, titanomagnete,
etc.); (2) bound with the argillaceous admixture;
(3) in the form of a film (usually illonite) adhering tightly
to the quartz grain; and (4) in the form of inclusions within
the quartz grain or as a part of some light silicates having a
specific gravity less than 3 (glauconite). Type 1 sands
should be treated by magnetic separation if the heavy
minerals are magnetic and by means of Wilfley, Devater, or
other tables if they are not magnetic. The type of table to
be used should be determined experimentally. Type 2
sands should be washed, using any desired washer. Type
3 sands are the most difficult to purify because the dense
film can be removed only by dissolving it. This method,
however, is not suitable for large quantities of sand. Experi-
ments at the State Institute of Glass have shown that
such films can be removed by grinding the sand; chemical
solution and mechanical "peeling" of the film have given
equal results as far as the removal of iron oxides is con-
cerned. Type 4 sands are seldom found in the pure state;
grains of this type have the iron oxides which remain after
any dressing operation. Sands of mixed types should be
treated by the combination of methods suitable for the
particular mixture.

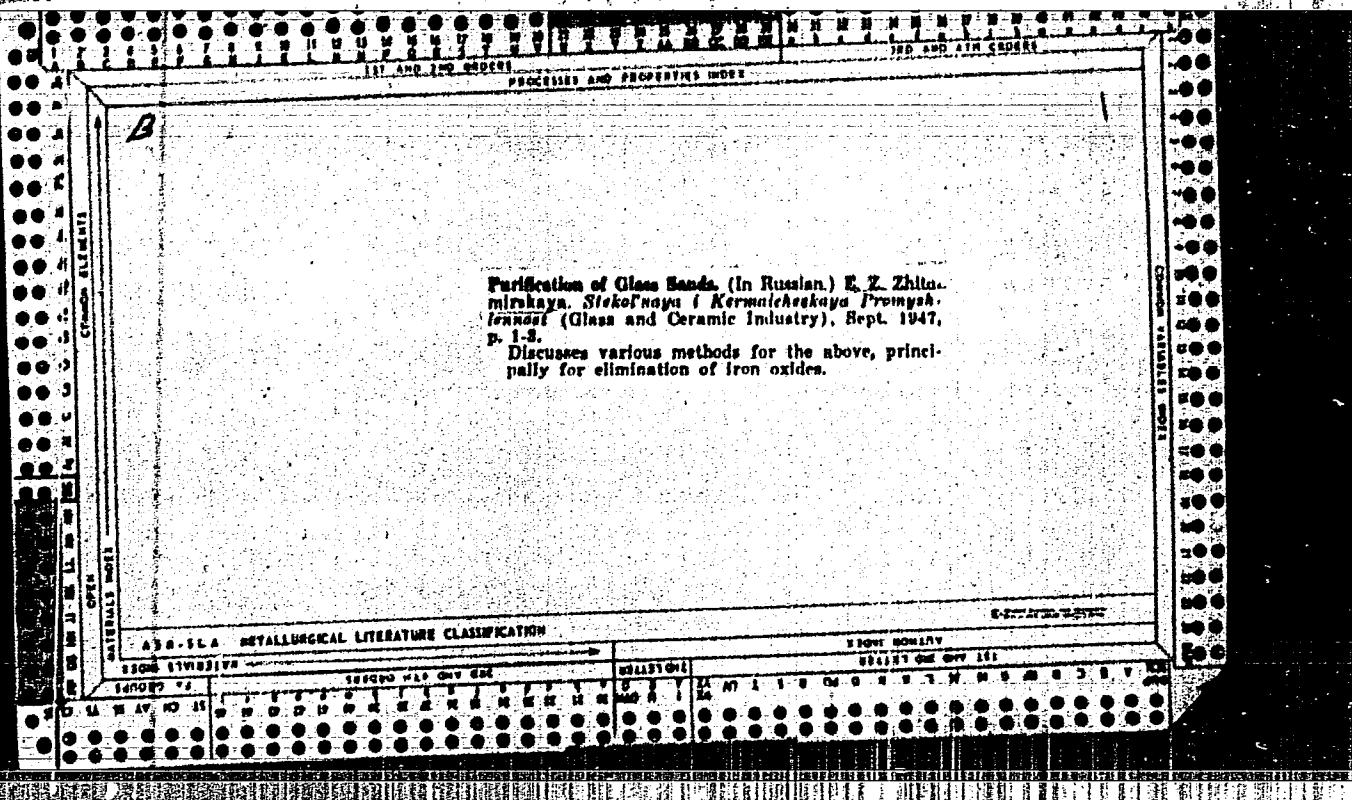

R.Z.K.

ZHITOMIRSKAYA, YE. Z.

Dressing of glass sands. II. Z. ZHITOMIRSKAYA
Slekol'naya i Keram. Prom., 1947, No. 9, pp. 1-6, 1-18.
Depending on the nature of the iron contamination, glass sands
are classified into types in which the iron compounds are
present (1) in the form of heavy minerals having a specific
gravity greater than 3 (magnetite, hematite, titanomagne-
tite, etc.); (2) bound with the argillaceous admixtures;
(3) in the form of a film (usually ilmenite) adhering tightly
to the quartz grain; and (4) in the form of some light silicates having a
specific gravity less than 3 (glauconite). Type 1 sands
should be treated by magnetic separation if the heavy
minerals are magnetic and by means of Wildley, Dryster, or
other tables if they are not magnetic. The type of table to
be used should be determined experimentally. Type 2
sands should be washed, using any desired washer. Type
3 sands are the most difficult to purify because the dense
film can be removed only by dissolving it; this method,
however, is not suitable for large quantities of sand. Ex-
periments at the State Institute of Glass have shown that
such films can be removed by pronouncing the sand) chemical
solution and mechanical "peeling" of the film have given
equal results as far as the removal of iron oxides is con-
cerned. Type 4 sands are seldom found in the pure state;
grains of this type have the iron oxides which remain after
any dressing operation. Sands of mixed types should be
treated by the combination of methods suitable for the
particular mixture. B.M.K.

Dressing of glass sands. Z. Zhurzhanaya
Slekol'nyye i Keram., 1947, No. 9, pp. 1-3-11.
Depending on the nature of the iron impurities, glass sands
are classified into types in which the iron compounds are
present (1) in the form of heavy minerals having a specific
gravity greater than 3 (magnetite, hematite, titanomagne-
tite, etc.); (2) bound with the argillaceous admixtures;
(3) in the form of a film (usually ilmenite) adhering tightly
to the quartz grain; and (4) in the form of inclusions within
the quartz grain or as a part of some light silicates having a
specific gravity less than 3 (glaucophane). Type 1 sands
should be treated by magnetic separation if the heavy
minerals are magnetite and by means of Wilfley, Deyster, or
other tables if they are not magnetic. The type of table to
be used should be determined experimentally. Type 2
sands should be washed, using any desired washer. Type
3 sands are the most difficult to purify because the dense
film can be removed only by dissolving it; this method,
however, is not suitable for large quantities of sand. Ex-
periments at the State Institute of Glass have shown that
such films can be removed by grinding the sand; chemical
solution and mechanical "peeling" of the film have given
equal results as far as the removal of iron oxides is con-
cerned. Type 4 sands are seldom found in the pure state;
grains of this type have the iron oxides which remain after
any dressing operation. Sands of mixed types should be
treated by the combination of methods suitable for the
particular mixture.

PROCESSING AND PROPERTIES OF...

BENEFICIATION OF SANDS FROM THE VELIKODVOR DEPOSITS.
 E. Z. Miltomirskaya and E. N. Stepanova. Abstracted in
Steklo i Tekhnika Promst. 1947, No. 7, pp. 17-18. —
 The quartz glass sands of the Velikodvor deposits analyze over
 98 SiO₂, about 0.10 TiO₂, up to 0.80 Al₂O₃, and up to 0.28%
 Fe₂O₃. Average grain size is 0.25 to 0.3 mm. The most
 effective method of treatment is by means of a Wifley table;
 this will remove 35 to 45% of the iron oxides (in one case,
 the removal was as high as 70%). The remaining content of
 iron oxides is 0.05 to 0.12%. The tailings are considerable
 but, after the dust has been removed, they can serve in the
 production of dark glass. The middlings were not treated
 further. Sands which are adulterated with iron in the form
 of limonite films on the grains must be treated by washing
 with friction in order to remove the iron. This method is
 equal to that involving the use of oxalic acid. B.Z.K.

Removal of iron from sands for the manufacture of glass of high transmissivity. K. Z. Zhitomirskaya and V. A. Shtilina. Abstracted in *Soviet Glass & Ceram. Proc.*, 1945, No. 4/5, 19; *Ceram. Abstracts* 1948, 9 (in *J. Am. Ceram. Soc.* 31, No. 1).—The Fe in the Lyubertsik sand is present in sand, up to 0.09%, but it is distributed in several mineralogical forms, which makes removal difficult. The extent of removal is better for the inferior sands of grade I than for the better sands of Grade U. By means of the Willey table the Fe content of Grade U can be lowered from 0.044 to 0.016%. The Fe in grade I can be reduced from 0.09 to 0.01-0.02% by treatment with AcOII, with or without the addition of copperas (medanterite). Consumption of AcOII should be 2.0 kg./ton of sand. The Fe content of grade I can also be reduced to 0.02% by means of the Willey table, but the loss is about 25%. The same results for grade I can also be obtained by the Adams method (AcONa in the presence of copperas and H_2SO_4), but the process is complicated and requires special equipment. In addition, to the removal of Fe, it is also necessary to eliminate all sources from which the Fe oxides can enter the glass melt to obtain glass of high transmissivity. M. P. R.

CH

Dewatering of quartz sands in centrifuges. E. Z. Zhukovskikh, and V. A. Mitina. Sov. i Krem. o, No. 8, 15-16/1969).—Quartz sands enriched by flotation-flotation and containing 8 to 10% moisture were successfully dewatered in a sugar-industry centrifuge operating at 900 r.p.m. and equipped with a 290 X 165-mm. rotor having about 500 openings of 8 mm. in diam. The residual moisture decreased with decreasing thickness of the sand layer and with increasing treatment; it ranged from 2.14% to 2.70%. For the glass industry, it is proposed to utilize periodic type, suspended centrifuges (model PM-1200) equipped with a 1200 X 500-mm. rotor and

unloading through the bottom. It is believed that continuous-type centrifuges will also be satisfactory.

B. Z. Kamich

Typical installations for dressing glass sands. V. V. ZAITOMIRSKAYA, Sibkrae R&D, a VNIIG (1940), reviews dressing methods. By means of flotation, the content of iron oxides was reduced in one sand from 0.11-0.17% to 0.03-0.06% and in another from 0.11% to 0.03-0.04%. This method is to be used only if the presence and distribution of the adulterants warrant it. A flow sheet of the flotation process is given. B.Z.K.

Typical installations for dressing glass sands. B. Z. Zhitonov, Nefte i Keram. 6, No. 4, 5-7 (1949); U. S. A. 2, 3576, 3578.—A review of methods. By means of flotation, it was possible to reduce the content of free carbon in one sand from 0.11-0.17% to 0.03-0.06%, and in another from 0.11% to 0.03-0.04%. The flotation method is to be used only if the presence and distribution of the adulterants warrant it. A flowsheet of the flotation process is given. B. Z. Kamich
